DESCRIPTION**BICYCLIC THIOPHENE DERIVATIVES AND USE AS GONADOTROPIN RELEASING HORMONE ANTAGONISTS**

5

Technical Field

The present invention relates to a pharmaceutical composition for antagonizing a gonadotropin-releasing hormone (GnRH) containing a condensed-bycyclic compound consisting of a homo or hetero 5 to 7-membered ring group and a homo or hetero 5 to 7-membered ring group. The present invention also relates to novel condensed-ring thiophene derivatives and salts thereof. The present invention further relates to methods for manufacturing the novel condensed-ring thiophene derivatives and the salts thereof.

Background Art

Secretion of anterior pituitary hormone undergoes the control by peripheral hormone secreted from target organs for the respective hormones and by secretion-accelerating or -inhibiting hormone from hypothalamus, which is the upper central organ of anterior lobe of pituitary (in this specification, these hormones are collectively called "hypothalamic hormone"). At the present stage, as hypothalamic hormones, nine kinds of hormones including, for example, thyrotropin releasing hormone (TRH) or gonadotropin releasing hormone {GnRH: sometimes called as LH-RH (luteinizing hormone releasing hormone)} are confirmed their existence (cf. Seirigaku 2, compiled by M. Iriku and K Toyama, published by Bunkohdo, p610-618, 1986). These hypothalamic hormones are assumed to show their actions via the receptor which is considered to exist in the anterior lobe of pituitary (cf. ibid), and observatinal studies of receptor genes specific to these hormones,

including cases of human, have been developed (Receptor Kiso To Rinshô, compiled by H. Imura, et al., published by Asakura Shoten, p297-304, 1993). Accordingly, antagonists or agonists specifically and selectively acting on these receptors control the action of hypothalamic hormone and controlling the secretion of anterior pituitary hormone. As the results, they are expected to be useful for prophylactic and therapeutic agents of anterior pituitary hormone dependent diseases.

Leuprorelin acetate [Fujino et al., Biological and Biophysical Research Communications, Vol.60, 00.406-413, 1974); Oliver, R.T.D. et al., British Journal of Cancers, Vol.59, p.823, 1989; and Toguchi et al., Journal of International Medical Research, Vol.18, pp.35-41], which is a highly potent derivative of gonadotropic hormone-releasing hormone, one of the hypothalamic hormones, (hereinafter sometimes abbreviated as GnRH) [Schally A. V. et al., Journal of Biological Chemistry, Vol. 246, pp.7230-7236, 1971; and Burgus, R. et al., Proceeding of Natural Academic Science, USA, Vol.69, pp278-282, 1972], by administration of multiple doses, lowers release. production of gonadotropic hormone in pituitary, causing lowering of reactivity on gonadotropic hormone in spermary and ovary to suppress secretion of testosterone and estrogen. Leuprorelin acetate has, therefore, been known to show antitumor activity on such hormone-dependent cancers as exemplified by prostate cancer, and has been widely used in the clinical field. Leuprorelin acetate has been widely used clinically also as a therapeutic agent of e.g. endometriosis and precocious puberty. The high antitumor activity of leuprorelin acetate is assumed to be due to its high resistance, as compared with natural GnRH, against protease, and to high affinity to

GnRH receptor causing desensitization of GnRH due to decrease in number of receptors. However, as leuporelin acetate is an ultra-agonist on GnRH receptor, it has been known that, immediately after the first administration, a transient aggravation accompanied with the rise of serum testosterone concentration due to pituitary-gonadotropic action (acute action) is observed. Circumstances being such as above, GnRH antagonistic drugs which are expected to have substantially the same therapeutic effects as described above but not to cause the above-mentioned transient pituitary-gonadotropic action (acute action) have been desired. As compounds having such GnRH antagonistic activity, a number of compounds including, for example, derivatives of GnRH such as straight-chain peptides, (USP 5140009, 5171835), cyclic hexapeptide derivatives [JPA S61(1986)-191698] or bicyclic peptide derivatives [Journal of medicinal chemistry, Vol.36, pp.3265-3273, 1993]. These compounds are, however, all peptides, which leave many problems including, for example, dosage forms, stability of drugs, durability of actions and stability on metabolism. For solving these problems, orally administrable GnRH antagonistic drugs, especially non-peptide ones, are strongly desired. At the present stage, however, no report on non-peptide GnRH antagonistic drugs has been made.

The object of the invention lies in providing novel compounds having excellent gonadotropic hormone releasing hormone antagonistic activity as well as excellent gonadotropic hormone releasing hormone antagonistic agents.

[Production Method 1]

In accordance with the method disclosed by K. Gewald, E. Schinke and H. Böttcher, Chem. Ber., 99, 94-100 (1966), an adequate ketone or aldehyde having an active methylene (i) was allowed to react with a cyanoacetic acid ester derivative and sulfur to convert into a 2-aminothiophene derivative (ii). More specifically, in the case of using ketone ($R^{1'} \neq H$), it is subjected to heating under reflux together with a cyanoacetic acid ester derivative, in the presence of acetic acid and ammonium acetate, in a proper solvent such as toluene to give an alkylidene cyanoacetic acid ester derivative, which is then heated in an adequate solvent, for example, ethanol in the presence of sulfur and a base to afford a 2-aminothiophene derivative (ii). And, in the case of using aldehyde ($R^{1'} = H$), it is heated in a proper solvent, for example, dimethylformamide, in the presence of a cyanoacetic acid ester derivative, sulfur and a base to give a 2-aminothiophene derivative (ii). The compound (ii) thus obtained is heated, in accordance with the method disclosed by Kuwata et al. [cf. German Patent 2,435,025], with diethyl ethoxymethylenemalonate to give an adduct (iii). The adduct is stirred in a

solvent, which does not give undesirable effect on the reaction, (e.g. alcohols such as ethanol and methanol), in the presence of a base (e.g. alkali metal hydroxide such as potassium hydroxide and sodium hydroxide) at
5 temperatures ranging from about 10 to 70°C to give carboxylic acid (iv). Then, the carboxylic acid (iv) thus obtained was subjected to ring-closure by heating in polyphosphoric acid ester (PPE) to give a thieno[2,3-b]pyridine derivative (v). The compound (v)
10 is stirred in a solvent, which does not give undesirable effect on the reaction, (e.g. amides such as dimethylformamide and dimethylacetamide), in the presence of a halogenated aralkyl derivative and a base (e.g. an organic base such as pyridine and
15 triethylamine) at temperatures ranging from about 10 to 100°C to give a 4,7-dihydro-4-oxothieno[2,3-b]pyridine-5-carboxylic acid ester derivative shown by the formula (Ia). Then, the compound (Ia) is stirred together with N-bromosuccinimide (NBS) in a solvent, which does not
20 give undesirable effect on the reaction, (e.g. halogenated hydrocarbons such as carbon tetrachloride and chloroform) in the presence of α, α' -azobisisobutyronitrile, at temperatures ranging from about 30 to 100°C to give a compound (Ib). The
25 compound (Ib) is stirred together with various amines in a solvent, which does not give undesirable effect on the reaction, (e.g. amides such as dimethylformamide and dimethylacetamide, nitrile such as acetonitrile and alcohols such as ethanol) in the presence of a base at
30 temperatures ranging from about 10 to 100°C to produce the compound (I). The production method 1 described above is shown in Scheme 1:

5 under heating in polyphosphoric acid ester (PPE) to give a thieno[2,3-b]pyridine derivative (ix). The compound (ix) is stirred together with a halogenated aralkyl derivative in a solvent, which does not affect adversely on the reaction, (e.g. amides such as

[Production Method 7]

In a proper solvent, which does not affect adversely on the reaction, (e.g. halogenated hydrocarbons such as dichloromethane; ethers such as tetrahydrofuran, ethyl ether and dioxane; and

pyridine), a 4,7-dihydro-5-hydroxymethylthieno[2,3-b]pyridine-4-one derivative (Ia") is stirred together with a suitable halogenating reagent (e.g. thionyl chloride and methanesulfonyl chloride) at temperatures ranging from about 0 to 100°C to give a 4,7-dihydrothieno[2,3-b]pyridine one derivative (Ig). The said derivative (Ig) is stirred, together with a suitable nucleophilic reagent, in a proper solvent, which does not affect adversely on the reaction, (e.g. ethers such as tetrahydrofuran and ethyl ether; and amides such as dimethylformamide) to give a corresponding 5-substituted derivative (Ih). The above production method 7 is shown in Scheme 7:

5 As the leaving group shown by the above X',

susceptible to substitution reaction by a nucleophilic
reagent [e.g. the hydrocarbon residue having a hetero-
atom with negative electric charge (e.g. oxygen
10 atom, sulfur atom and nitrogen atom) shown by the
above YR^{16}]. More specifically, for example,
aralkyloxy (e.g. acetoxy), alkylsulfonyloxy (e.g.
methanesulfonyloxy) and alkyl-aryl sulfonyloxy (e.g. p-
toluenesulfonyloxy) are mentioned.

15 The hydrocarbon residue in the nitrogen atom

mentioned above has the same meaning as defined in
reference to the hydrocarbon residue in the carbonyl
group optionally substituted with hydrocarbon residue
20 shown by the above-mentioned R⁴.

[Production Method 8]

In a proper solvent, which does not affect
adversely on the reaction, (e.g. ethers such as
tetrahydrofuran, ethyl ether and dioxane; and
25 pyridine), 4,7-dihydro-5-formylthieno[2,3-b]pyridine-4-
one derivative (Ih) is stirred together with a suitable
Wittig reagent at temperatures ranging from about 0 to
100°C to give a 4,7-dihydrothieno[2,3-b]pyridine-4-one
derivative (Ij). The said derivative (Ij) is stirred
30 at temperatures ranging from about 10 to 100°C together
with a suitable reducing reagent [e.g. hydrogenation
using, in hydrogen streams, a catalyst (e.g. palladium-
carbon catalyst)] in a proper solvent, which does not
affect adversely on the reaction (e.g. alcohols such as
35 ethyl alcohol, esters such as acetic acid ethyl ester,
ethers such as tetrahydrofuran, ethyl ether and

dimethylformamide) to give a corresponding 5-substituted derivative (Ik). The above production method 8 is shown in Scheme 8:

[Production Method 9]

In a proper solvent, which does not affect adversely on the reaction, (e.g. ethers such as tetrahydrofuran and dioxane; and alcohols such as ethyl alcohol), 4,7-dihydro-4-oxothieno[2,3-b]pyridine-5-carboxylic acid ester derivative (Id') is subjected to hydrolysis under stirring at temperatures ranging from about 10 to 100°C by adding an acid (e.g. inorganic acid such as hydrochloric acid) or an alkaline aqueous solution (e.g. 1-4N aqueous solution of alkali metal hydroxide such as sodium hydroxide, potassium hydroxide and lithium hydroxide). The resulting 5-carboxylic acid derivative is heated at temperatures ranging from about 50 to 200°C in a proper solvent, which does not affect adversely on the reaction, to give a corresponding decarboxylated derivative (In). [Production Method 10]

Starting from the 2-aminothiophene derivative (ii), the urea derivative (II) was produced by, for example, the following method A or B.

1. Method A: The 2-aminothiophene derivative (ii) produced by the method described in Production Method 1 or a salt thereof is allowed to react with an isocyanate derivative. The isocyanate derivative is exemplified by derivatives represented by the formula, $R^{12}-NCO$ (wherein R^{12} is of the same meaning as defined above). The reaction of the compound (ii) or a salt thereof with the isocyanate derivative is conducted in an solvent which does not adversely affect on the reaction (e.g. tetrahydrofuran, pyridine, dioxane, benzene, dichloromethane, 1,2-dichloroethane, toluene, xylene) at temperatures ranging from about 15 to about 130°C. The isocyanate derivative is employed in an amount of about 1 to 5 equivalents, preferably about 1.1 to 2.5 equivalents, relative to 1 equivalent of the compound (ii). The reaction time ranges from several hours to several days, preferably from about 15 minutes to about two days.

2. Method B: Amine [e.g. a compound represented by the formula $R^{12}-NH_2$ (wherein R^{12} is of the same meaning as defined above)] is subjected to addition reaction to an isocyanate derivative produced by allowing a 2-aminothiophene derivative (ii) or a salt thereof to react with phosgene or an equivalent compound thereof [e.g. diphosgene such as bis(trichloromethyl)carbonate, triphosgene such as trichloromethylchloroformate]. The reaction of the compound (ii) or a salt thereof with phosgene or an equivalent compound thereof is conducted in a solvent which does not affect adversely on the reaction (e.g. dioxane, tetrahydrofuran, benzene,

toluene, xylene, 1,2-dichloroethane, chloroform) at temperatures ranging from about 40 to 120°C. Phosgene or an equivalent compound thereof is employed in an amount ranging from about 0.5 to 2 equivalents, preferably from about 0.9 to 1.1 equivalent). The reaction time ranges from several minutes to several days, preferably from about 15 minutes to about two days. The addition reaction of amine is conducted in a solvent which does not affect adversely on the reaction (e.g. pyridine, tetrahydrofuran, dioxane, benzene, dichloromethane, 1,2-dichloroethane, toluene, xylene) at temperatures ranging from about 15 to 130°C. Amine is employed in an amount ranging from about 1 to 5 equivalents, preferably from about 1.1 to 3 equivalents. The reaction time ranges from several minutes to several days, preferably from about 15 minutes to about two days.

The compound (XV) or a salt thereof thus produced is processed with a base to cause ring-closure reaction to thereby produce a thieno [2,3-d] pyrimidine derivative (XVI). The ring-closure reaction is conducted in a solvent which does not affect adversely on the reaction. The solvent is exemplified by alcohols such as methanol, ethanol or propanol, and ethers such as dioxane or tetrahydrofuran.

As the base, use is made of, for example, an alkali metal alkoxide such as sodium methyllate, sodium ethyllate or sodium isopropoxide, and an alkali metal hydride such as sodium hydride.

The amount of the base to be employed ranges from 1 to 5 equivalents, preferably from about 1.5 to 3 equivalents, relative to 1 equivalent of the compound (XV).

The reaction temperature ranges from about 10°C to the boiling point of the solvent then employed, preferably from about 25°C to the boiling point of the

solvent then employed.

The reaction time ranges from several minutes to several days, preferably from about 10 minutes to two days.

5 The compound (XVI) and a halogenated aralkyl derivative are stirred, in the presence of a base (e.g. an organic base such as pyridine or triethylamine), in a solvent which does not affect adversely on the reaction (e.g. amides such as dimethylformamide or
10 dimethylacetamide), at about 10 to 100°C, to produce a 2,4-dioxothieno[2,3-d]pyrimidine derivative (IIa). Subsequently, the said compound (IIa) is stirred together with N-bromosuccinimide (NBS) in a solvent which does not affect adversely on the reaction (e.g.
15 halogenated hydrocarbons such as carbon tetrachloride or chloroform), in the presence of α , α' -azobisisobutyronitrile, to thereby produce the compound (IIb). Further, the said compound is stirred together with various amines, in the presence of a base, in a
20 solvent which does not affect adversely on the reaction (e.g. amides such as dimethylformamide or dimethylacetamide, nitriles such as acetonitrile, alcohols such as ethanol), at temperatures ranging from about 10 to 100°C, to thereby produce the compound
25 (II). When necessary, the said compound is made into a corresponding salt with a suitable acid (e.g. hydrochloric acid or oxalic acid).

The foregoing Production Method 10 is shown by Scheme 10:

25 about 30 to 120°C, to cause dehydro-cyclization to thereby produce a derivative (VIIa). The said compound was stirred, together with a halogenated aralkyl derivative, in the presence of a base (e.g. organic bases including potassium carbonate, pyridine and

preparing pharmaceutical compositions.

The compound of the present invention or a salt thereof can be made into injections either in a form of an aqueous injection together with dispersing agents
5 [e.g. Tween 80 (Atlas Powder, U.S.A.), HCO 80 (Nikko Chemicals, Japan), polyethylene glycol, carboxymethylcellulose, sodium alginate, etc.], preservatives (e.g. methyl paraben, propyl paraben, benzyl alcohol, etc.), isotonizing agents (e.g. sodium
10 chloride, mannitol, sorbitol, glucose, etc.) and the like or in a form of an oily injection by dissolving, suspending or emulsifying in plant oil (e.g. olive oil, sesame oil, cotton seed oil, corn oil, etc.), propylene glycol and the like.

15 In preparing a pharmaceutical composition for oral use, the compound of the present invention or a salt thereof is molded by compressing, for example, with fillers (e.g. lactose, sucrose, starch, etc.), disintegrating agents (e.g. starch, calcium carbonate,
20 etc.), binders (e.g. starch, gum arabic, carboxymethylcellulose, polyvinylpyrrolidone, hydroxypropylcellulose, etc.) or lubricants (e.g. talc, magnesium stearate, polyethylene glycol 6000, etc.) and the like. If necessary, the composition is coated by a
25 per se known method with an object of masking the taste, enteric coating or long-acting. Examples of the coating agent therefore are hydroxypropylmethylcellulose, ethylcellulose, hydroxymethylcellulose, hydroxypropylcellulose,
30 polyoxyethylene glycol, Tween 80, pluronic F 68, cellulose acetate phthalate, hydroxypropylmethylcellulose phthalate, hydroxymethylcellulose acetate succinate, Eudragit (a copolymer of methacrylic acid with acrylic acid;
35 manufactured by Rohm, Germany), red oxide of iron and the like. Subcoating layer may be provided between the

enteric coating and the core according to per se known method.

In preparing an external composition, the compound of the present invention or a salt thereof as it is or
5 a salt thereof is subjected to a per se known method to give a solid, semisolid or liquid agent for external use. For example, the solid preparation is manufactured as follows. Thus, the compound of the present invention as it is or after adding/mixing
10 fillers (e.g. glycol, mannitol, starch, microcrystalline cullulose, etc.), thickeners (e.g. natural gums, cellulose derivatives, acrylic acid polymers, etc.) and the like thereto/therewith is made into a powdery composition. With respect to the liquid
15 composition, an oily or aqueous suspension is manufactured by the manner nearly the same as in the case of the injection. In the case of a semisolid composition, the preferred one is an aqueous or oily gel or an ointment. Each of them may be compounded
20 with a pH adjusting agent (e.g. carbonic acid, phosphoric acid, citric acid, hydrochloric acid, sodium hydroxide, etc.), an antiseptic agent (e.g. p-hydroxybenzoates, chlorobutanol, benzalkonium chloride, etc.) and the like.

25 In the manufacture of an ointment for example, the compound of the present invention or a salt thereof can be made into an oily or an aqueous solid, semisolid or liquid ointment. Examples of the oily base material applicable in the above-mentioned composition are
30 glycerides of higher fatty acids [e.g. cacao butter, Witepsols (manufactured by Dynamite-Nobel), etc.], medium fatty acids [e.g. Miglyols (manufactured by Dynamite-Nobel), etc.] and plant oil (e.g. sesame oil, soybean oil, cotton seed oil, etc.) and the like.
35 Examples of the aqueous base material are polyethylene glycols and propylene glycol and those of the base

material for aqueous gel are natural gums, cellulose derivatives, vinyl polymers, acrylic acid polymers, etc.

Best Mode for Carrying Out of the Invention

By way of the following Reference Examples, Working Examples and Test Examples, the present invention will be described more specifically, but they are not intended to limit the scope of this invention thereto.

¹H-NMR spectra were taken with the Varian GEMINI 200 (200 MHz) type spectrometer, JEOL LAMBDA300 (300MHz) type spectrometer or the Bruker AM 500 (500 MHz) type spectrometer, employing tetramethylsilane as the internal standard. All delta values were expressed in ppm.

The symbols used in the present specification have the following meanings:

s: singlet, d: doublet, t: triplet, dt: double triplet, m: multiplet, br: broad

Reference Example 1

2-Amino-5-phenylthiophene-3-carboxylic acid ethyl ester

To a mixture of ethyl cyanoacetate (6.1 g, 50 mmol), sulfur (1.61 g, 50 mmol) triethylamine (3.5 ml, 25 mmol) and dimethylformamide (10 ml) was added dropwise, with stirring at 45°C, phenylacetaldehyde (50% diethylphthalate solution; 12.05 g, 50 mmol) for 20 minutes. The mixture was stirred for 9 hours at 45°C, and the reaction mixture was concentrated. The resulting residue was extracted with ethylacetate. The extract was washed with an aqueous sodium chloride solution, which was then dried (MgSO₄), followed by distilling off the solvent under reduced pressure. To a solution of the compound produced in Reference Example 11 (0.12 g, 0.40 mmol) in dimethylformamide (10 ml) were added, at room temperature, potassium carbonate (0.083 g, 0.60 mol), 2-methoxybenzyl chloride (0.094 g, 0.60 mol) and potassium iodide (0.033 g, 0.20 mmol). The mixture was stirred for 90 minutes at room temperature, and then for 2 hours at 50°C. The reaction mixture was concentrated, and the concentrate was partitioned between dichloromethane and water. The aqueous layer was extracted with dichloromethane. The extract was washed with an aqueous sodium chloride solution, which was then dried (MgSO₄), then the solvent was distilled off under reduced pressure. The residue was chromatographed on silica gel to give a pale yellow amorphous, which was recrystallized from ethyl acetate to afford colorless crystals, m.p.153-156°C.

The compound produced in Working Example 33 (0.25 g) was dissolved in dimethylformamide (20 ml). To the solution were added, at room temperature, diisopropyl ethylamine (0.079 g) and N-benzylmethylamine (0.074 g). The mixture was stirred for 90 minutes at room temperature. The reaction mixture was concentrated to

dryness under reduced pressure. The residue was partitioned between ethyl acetate (100 ml) and a saturated aqueous solution of sodium hydrogencarbonate (50 ml). The aqueous layer was extracted with ethyl acetate (100 ml). The combined organic layer was dried. The solvent was distilled off, and the residue was chromatographed on silica gel to give a yellow amorphous (0.27 g). The amorphous was dissolved in methylene chloride (5 ml), to which was added, with ice-cooling, an 1N solution of hydrogen chloride in ether (1 ml). The resulting crystalline precipitate was collected by filtration to give a titled compound (0.22 g, yield 77%), m.p.185-193°C.
